1 Data Structures

1.1 UFDS

Construction: $O(n)$
Union Find with Path Compression: $\approx O(1)$
Union Find Data Structure, or Disjoint Set, uses an array ***id*** to keep track of the root of the set of each element. The following implementation is **0-indexed**.

```
1  class UnionFind {
2
3      public:
4          vector<int> id, size;
5          int components;
6          UnionFind(int n){
7              for (int i = 0; i < n; i++){
8                  id.push_back(i);
9                  size.push_back(1);
10             }
11             components = n;
12         }
13
14         int find(int a){
15             int root = a;
16             while (id[root] != root) {
17                 root = id[root];
18             }
19
20             //Path compression
21             while (a != root){
22                 int next = id[a];
23                 id[a] = root;
24                 a = next;
25             }
26
27             return root;
28         }
29
30         void unite(int a, int b){
31             int root_a = find(a), root_b = find(b);
32             if (root_a == root_b){
33                 return;
34             }
35
36             if (size[root_a] > size[root_b]){
37                 id[root_b] = root_a;
38                 size[root_a] += size[root_b];
39             } else {
40                 id[root_a] = root_b;
41                 size[root_b] += size[root_a];
42             }
43
44             components--;
45         }
46
```

```
47          bool connected(int a, int b){ return find(a) == find(b);}
48
49          int getSize(int a){return size[find(a)];}
50  };
```

2 Algorithms

2.1 Sieve of Erastothenes

Construction: $O(n \log \log n)$
Generates a vector of every prime number $\leq limit$. The basic idea behind the Sieve of Eratosthenes is that at each iteration one prime number is picked up and all its multiples are eliminated. After the elimination process is complete, all the unmarked numbers that remain are prime.

```
1  vector<bool> sieve_erastothenes(unsigned ll limit){
2      vector<bool> prime(limit, true);
3      for (int p = 2; p*p <= limit; p++){
4          if (prime[p]){
5              for (int i = p*p; i <= limit; i += p){
6                  prime[i] = false;
7              }
8          }
9      }
10
11     return prime;
12 }
```

2.2 Number of Divisors

Returns the number of distinct divisors of a number using the sieve of erastothenes.

```
1  int num_divisors(ll n){
2      vector<ll> primes = sieve_erastothenes(n);
3      int total = 1;
4      for (ll p : primes){
5          int count = 0;
6          while (n % p == 0){
7              n = n / p;
8              count++;
9          }
10         total *= (count + 1);
11     }
12
13     return total;
14 }
```

Listing 1: https://www.geeksforgeeks.org/total-number-divisors-given-number/

2.3 Fast Primality Check

```
1  bool is_prime(ll n) {
2      if (n <= 1)  return false;
3      if (n <= 3)  return true;
4      if (n % 2 == 0 || n % 3 == 0) return false;
```

```
5
6       for (ll i = 5; i * i <= n; i += 6)
7           if (n % i == 0 || n % (i+2) == 0)
8              return false;
9
10      return true;
11  }
```

2.4 Generate All Subsets

Runtime: $O(2^n)$

```
1   vector<vector<int>> all_subsets(vector<int> vec){
2       vector<vector<int>> subsets;
3       int n = vec.size();
4       // 1 << n is the same as 2**n
5       for (int i = 0; i < (1 << n); i++){
6           subsets.push_back(vector<int>());
7           for (int j = 0; j < n; j++){
8               if (i & (1 << j)){ //check if bit j is set
9                   subsets.back().push_back(vec[j]);
10              }
11          }
12      }
13      return subsets;
14  }
```

3 Misc

3.1 Program Structure

```
1   #include <bits/stdc++.h>
2   using namespace std;
3   #define ll long long
4
5   int main(){
6     ios::sync_with_stdio(0), cin.tie(0); //Fast IO
7   }
```

3.2 Runtime Bounds

1 second : $\leq 10^8$ operations 5 seconds : $\leq 10^9$ operations

n	Bound
$\leq [10..11]$	$O(n!), O(n^6)$
≤ 22	$O(2^n)$
≤ 100	$O(n^4)$
≤ 400	$O(n^3)$
$\leq 10K$	$O(n^2)$
$\leq 1M$	$O(n \log_2 n)$
$\geq 1M$	$O(n)$

3.3 Bitmasks

Operation	Result
Right Shift >>	Shift bits n places to the right. Equivalent to dividing by 2^n
Left Shift <<	Shift bits n places to the left. Equivalent to multiplying by 2^n
NOT $\sim$	Flips each bit
OR |	OR's each bit. Binary operator, requires two different numbers
AND &	AND's each bit. Binary operator, requires two different numbers
XOR ^	XOR's each bit. Binary operator, requires two different numbers

Note: Never do bitwise operations on a signed integer!

3.4 Math

Properties of Mod

- $(a + b) \bmod m = (a \bmod m + b \bmod m) \bmod m$
- $(a * b) \bmod m = (a \bmod m * b \bmod m) \bmod m$

3.5 STL Data Structures

- **vector**: Random access, amortized $O(1)$ insertion at end
- **deque**: $O(1)$ insertion and deletion at ends, **has $O(1)$ random access also!**
- **stack/queue**: Provides an interface that wraps around deque
- **bitset**: Optimized array of booleans
- **map, unordered_map, set**
- **multiset**: Set with duplicates
- **priority_queue**: Max heap

3.6 STL Algorithms

- **Sorting:**
  - `sort`
  - `partial_sort`: Sorts a range $[i..j]$ as if sorting normally. However, elements not in $[i..j]$ are in unspecified order.
  - `stable_sort`: Maintain initial order of items that are equal
- **Searching:**
  - `lower_bound`: Iterator pointing to first element $\geq$ `val`. Must be sorted beforehand. `lower_bound(10) ->` $[1, \mathbf{10}, 10, 10, 23]$. $O(\log n)$ runtime.
  - `upper_bound`: Same as `lower_bound` but returns first element $>$ `val`. `upper_bound(10) ->` $[1, 10, 10, 10, \mathbf{23}]$. If an array is sorted, the distance between two elements can be calculated by `upper_bound - lower_bound` using pointer arithmetic.
  - `binary_search`:
- **Other:**
  - `next_permutation`: Generates next lexicographically greater permutation. Can be used to generate every ordering if array is sorted beforehand. `prev_permutation` also exists.
  - `partial_sum`: Generates prefix sum array

3.7 Debug a segfault

```
g++ -g program.cpp
gdb ./a.out
run
backtrace
```
